

# Measure change under conditioning

## 1 Setup and notation

- Let  $\mathbf{D} = (D^-, D^+)$  a  $\mathbb{N} \times \mathbb{N}$ -valued random variable and let

$$\mu := \mathbb{E}[D^-] = \mathbb{E}[D^+] \quad (1)$$

$$\beta_- := \mathbb{E}[(D^-)^2] \quad (2)$$

$$\gamma_- := \mathbb{E}[(D^-)^3] \quad (3)$$

$$\rho := \mathbb{E}[D^- D^+] \quad (4)$$

- Let  $\mathbf{D}_1, \dots, \mathbf{D}_n$  be i.i.d. copies of  $\mathbf{D}$  let

$$\Xi_{n-m}^\pm := \sum_{i=m+1}^n D_i^\pm \quad (5)$$

$$\Delta_{n-m} := \Xi_{n-m}^- - \Xi_{n-m}^+. \quad (6)$$

- Let  $\Sigma_n$  be a sized biased ordering of  $\mathbf{D}_1, \dots, \mathbf{D}_n$  be in-degree. Ririgously  $\Sigma_n$  is a random permutation on  $\{1, \dots, n\}$  such that

$$\mathbb{P}(\Sigma_n = \sigma \mid D_1^- = k_1^-, \dots, D_n^- = k_n^-) := \prod_{i=1}^n \frac{k_{\sigma(i)}^-}{\sum_{j=i}^n k_{\sigma(j)}^-}. \quad (7)$$

- Let  $(\hat{\mathbf{D}}_{n,1}, \dots, \hat{\mathbf{D}}_{n,n}) := (\mathbf{D}_{\Sigma_n(1)}, \dots, \mathbf{D}_{\Sigma_n(n)})$ .
- Let  $\mathbf{Z}_1, \mathbf{Z}_2, \dots$  be i.i.d. with law

$$\mathbb{P}(Z_i^- = k^-, Z_i^+ = k^+) := \frac{1}{\mu} k^- \mathbb{P}(D^- = k^-, D^+ = k^+). \quad (8)$$

Then

$$\nu_- := \mathbb{E}[Z_i^-] = \frac{\beta_-}{\mu} \quad (9)$$

$$\nu_+ := \mathbb{E}[Z_i^+] = \frac{\rho}{\mu} \quad (10)$$

## 2 Exact form of the measure change

First we state the form of the measure change between  $\hat{\mathbf{D}}_{n,1}, \dots, \hat{\mathbf{D}}_{n,m}$  and  $\mathbf{Z}_1, \dots, \mathbf{Z}_m$ . The proof of [1, Proposition 4.2] covers the undirected configuration model but the same proof works for the directed case.

### Theorem 1

For any test function  $u : (\mathbb{N} \times \mathbb{N})^m \rightarrow \mathbb{R}$ ,

$$\mathbb{E}[u(\hat{\mathbf{D}}_{n,1}, \dots, \hat{\mathbf{D}}_{n,m})] = \mathbb{E}[u(\mathbf{Z}_1, \dots, \mathbf{Z}_m) \psi_m^n(\mathbf{Z}_1, \dots, \mathbf{Z}_m)] \quad (11)$$

where

$$\psi_m^n(\mathbf{k}_1, \dots, \mathbf{k}_m) := \mathbb{E} \left[ \prod_{i=1}^m \frac{(n-i+1)\mu}{\sum_{j=i}^n k_j^- + \Xi_{n-m}^-} \right]. \quad (12)$$

Now we give the form of the measure change after conditioning on the event

$$\{\Delta_n = 0\} = \left\{ \sum_{i=1}^n \hat{D}_{n,i}^- = \sum_{i=1}^n \hat{D}_{n,i}^+ \right\} = \left\{ \sum_{i=1}^n D_i^- = \sum_{i=1}^n D_i^+ \right\}. \quad (13)$$

### Theorem 2

For any test function  $u : (\mathbb{N} \times \mathbb{N})^m \rightarrow \mathbb{R}$ ,

$$\mathbb{E} \left[ u(\hat{\mathbf{D}}_{n,1}, \dots, \hat{\mathbf{D}}_{n,m}) \mid \Delta_n = 0 \right] = \mathbb{E}[u(\mathbf{Z}_1, \dots, \mathbf{Z}_m) \phi_m^n(\mathbf{Z}_1, \dots, \mathbf{Z}_m)] \quad (14)$$

where

$$\phi_m^n(\mathbf{k}_1, \dots, \mathbf{k}_m) = \frac{\mathbb{E} \left[ \prod_{i=1}^m \frac{(n-i+1)\mu}{\sum_{j=i}^n k_j^- + \Xi_{n-m}^-} \mathbb{1} \{ \Delta_{n-m} = \sum_{i=1}^m (k_i^+ - k_i^-) \} \right]}{\mathbb{P}(\Delta_n = 0)}. \quad (15)$$

*Proof.* By theorem 1, since

$$\psi_m^n(\mathbf{k}_1, \dots, \mathbf{k}_m) = \prod_{i=1}^m \frac{(n-i+1)\mu}{\sum_{j=i}^n k_j^-} \quad (16)$$

we have

$$\mathbb{E} \left[ u(\hat{\mathbf{D}}_{n,1}, \dots, \hat{\mathbf{D}}_{n,m}) \mathbb{1} \left\{ \sum_{i=1}^n (\hat{D}_{n,i}^- - \hat{D}_{n,i}^+) = 0 \right\} \right] \quad (17)$$

$$= \mathbb{E} \left[ u(\mathbf{Z}_1, \dots, \mathbf{Z}_m) \mathbb{1} \left\{ \sum_{i=1}^n (Z_i^- - Z_i^+) = 0 \right\} \prod_{i=1}^n \frac{(n-i+1)\mu}{\sum_{j=i}^n Z_j^-} \right] \quad (18)$$

$$= \mathbb{E} \left[ u(\mathbf{Z}_1, \dots, \mathbf{Z}_m) \mathbb{E} \left[ \mathbb{1} \left\{ \sum_{i=m+1}^n (Z_i^- - Z_i^+) = \sum_{i=1}^m (Z_i^+ - Z_i^-) \right\} \right. \right. \\ \left. \left. \times \prod_{i=1}^m \frac{(n-i+1)\mu}{\sum_{j=i}^m Z_j^- + \sum_{j=m+1}^n Z_j^-} \prod_{i=m+1}^n \frac{(n-i+1)\mu}{\sum_{j=i}^n Z_j^-} \mid \mathbf{Z}_1, \dots, \mathbf{Z}_m \right] \right]. \quad (19)$$

Thus eq. (14) holds with

$$\phi_m^n(\mathbf{k}_1, \dots, \mathbf{k}_m) = \frac{1}{\mathbb{P}(\Delta_n = 0)} \mathbb{E} \left[ \mathbb{1} \left\{ \sum_{i=m+1}^n (Z_i^- - Z_i^+) = \sum_{i=1}^m (k_i^+ - k_i^-) \right\} \right. \\ \left. \times \prod_{i=1}^m \frac{(n-i+1)\mu}{\sum_{j=i}^m k_j^- + \sum_{j=m+1}^n Z_j^-} \prod_{i=m+1}^n \frac{(n-i+1)\mu}{\sum_{j=i}^n Z_j^-} \right]. \quad (20)$$

Since the  $Z_i$  are i.i.d. we can shift indices to get

$$\phi_m^n(\mathbf{k}_1, \dots, \mathbf{k}_m) = \frac{1}{\mathbb{P}(\Delta_n = 0)} \mathbb{E} \left[ \mathbb{1} \left\{ \sum_{i=1}^{n-m} (Z_i^- - Z_i^+) = \sum_{i=1}^m (k_i^+ - k_i^-) \right\} \right. \\ \left. \times \prod_{i=1}^m \frac{(n-i+1)\mu}{\sum_{j=i}^m k_j^- + \sum_{j=1}^{n-m} Z_j^-} \prod_{i=1}^{n-m} \frac{(n-m-i+1)\mu}{\sum_{j=i}^{n-m} Z_j^-} \right]. \quad (21)$$

Note that

$$\prod_{i=1}^{n-m} \frac{(n-m-i+1)\mu}{\sum_{j=i}^{n-m} Z_j^-} = \psi_{n-m}^{n-m}(\mathbf{Z}_1, \dots, \mathbf{Z}_{n-m}) \quad (22)$$

therefore by theorem 1

$$\phi_m^n(\mathbf{k}_1, \dots, \mathbf{k}_m) = \frac{1}{\mathbb{P}(\Delta_n = 0)} \mathbb{E} \left[ \mathbb{1} \left\{ \sum_{i=1}^{n-m} (\hat{D}_{n-m,i}^- - \hat{D}_{n-m,i}^+) = \sum_{i=1}^m (k_i^+ - k_i^-) \right\} \right. \\ \left. \times \prod_{i=1}^m \frac{(n-i+1)\mu}{\sum_{j=i}^m k_j^- + \sum_{j=1}^{n-m} \hat{D}_{n-m,j}^-} \right]. \quad (23)$$

Finally since

$$\sum_{i=1}^{n-m} \hat{D}_{n-m,i}^\pm = \sum_{i=1}^{n-m} D_i^\pm \stackrel{d}{=} \sum_{i=m+1}^n D_i^\pm = \Xi_{n-m}^\pm \quad (24)$$

we obtain the desired result of

$$\phi_m^n(\mathbf{k}_1, \dots, \mathbf{k}_m) = \frac{\mathbb{E} \left[ \prod_{i=1}^m \frac{(n-i+1)\mu}{\sum_{j=i}^n k_j^- + \Xi_{n-m}^-} \mathbf{1} \{ \Delta_{n-m} = \sum_{i=1}^m (k_i^+ - k_i^-) \} \right]}{\mathbb{P}(\Delta_n = 0)}. \quad (25)$$

□

### 3 Approximation of the measure change

We explore the scaling of the measure change  $\phi_m^n$  as  $n \rightarrow \infty$  in the regime  $m(n) = \Theta(n^{2/3})$ .

#### Theorem 3

Define

$$s^\pm(i) := \sum_{j=1}^i (k_j^\pm - \nu_\pm). \quad (26)$$

1. Assume  $\mathbf{k}_1, \dots, \mathbf{k}_m$  satisfies

$$\max_{i=1, \dots, m} |s^\pm(i)| \leq m^{\frac{1}{2} + \epsilon}. \quad (27)$$

2. Assume  $D^- - D^+$  is not supported on any proper sublattice of  $\mathbb{Z}$ , in that for all  $a, b \in \mathbb{Z}$  if  $b \geq 2$  then

$$\mathbb{P}(D^- - D^+ \in a + b\mathbb{Z}) < 1. \quad (28)$$

Then in the regime  $m = \Theta(n^{2/3})$

$$\phi_m^n(\mathbf{k}_1, \dots, \mathbf{k}_m) \geq \exp \left( \frac{1}{\mu n} \sum_{i=0}^m (s^-(i) - s^-(m)) - \frac{\sigma_-^2}{6\mu^2} \frac{m^3}{n^2} \right) + o(1) \quad (29)$$

where the  $o(1)$  term is independent of  $\mathbf{k}_1, \dots, \mathbf{k}_m$  satisfying our assumptions.

This result only provides a lower bound, but this proves to be sufficient since we can show asymptotically that the lower bound has expectation 1. This shows we haven't lost a significant amount of mass in the limit. The condition on  $\mathbf{k}_1, \dots, \mathbf{k}_m$  occurs with high probability when  $\mathbf{k}_i = \mathbf{Z}_i$  since the  $s^-$  and  $s^+$  become centered random walks.

#### 3.1 Exponential tilting

Note that  $Z^- - Z^+$  is non-centered so we expect  $\sum_{i=1}^m (k_i^+ - k_i^-)$  to be of order  $m$ . This is a moderate deviation event for  $\Delta_{n-m}$ . To deal with this, we tilt the measure exponentially so that  $\Delta_{n-m}$  has mean approximately  $\sum_{i=1}^m (k_i^+ - k_i^-)$ .

The next result defines the tilting and then gives asymptotics for cumulant generating function of  $D^-$  and for the behaviour of  $\Xi_{n-m}^-$  and  $\Xi_{n-m}^+$  under this tilting.

**Lemma 1**

Define an measure  $\mathbb{P}_\theta$ , for  $\theta \geq 0$ , by its Radon–Nikodym derivative

$$\frac{d\mathbb{P}_\theta}{d\mathbb{P}} := \exp(-\theta D^- - \alpha(\theta)) \quad \text{where} \quad \alpha(\theta) := \log \mathbb{E} \left[ e^{-\theta D^-} \right]. \quad (30)$$

Then as  $\theta \downarrow 0$  we have

$$\alpha(\theta) = -\mu\theta + \frac{1}{2} \text{var}(D^-)\theta^2 - \frac{1}{6} \mathbb{E}[(D^- - \mu)^3] \theta^3 + o(\theta^3), \quad (31)$$

$$\mathbb{E}_\theta[D^-] = \mu - \text{var}(D^-)\theta + \frac{1}{2} \mathbb{E}[(D^- - \mu)^3] \theta^2 + o(\theta^2), \quad (32)$$

$$\mathbb{E}_\theta[D^+] = \mu - \text{cov}(D^-, D^+)\theta + \frac{1}{2} \mathbb{E}[(D^- - \mu)^2(D^+ - \mu)] \theta^2 + o(\theta^2), \quad (33)$$

$$\text{var}_\theta(D^-) = \text{var}(D^-) - \mathbb{E}[(D^- - \mu)^3] \theta + o(\theta), \quad (34)$$

$$\text{var}_\theta(D^+) = \text{var}(D^+) - \mathbb{E}[(D^- - \mu)(D^+ - \mu)^2] \theta + o(\theta), \quad (35)$$

$$\text{cov}_\theta(D^-, D^+) = \text{cov}(D^-, D^+) + \mathbb{E}[(D^- - \mu)^2(D^+ - \mu)] \theta + o(\theta). \quad (36)$$

*Proof.* Since  $\mathbb{E}[|D^-|^3] < \infty$  and  $D^-$  is non-negative, by the dominated convergence theorem

$$\mathbb{E}[(D^-)^3 \exp(-\theta D^-)] = \mathbb{E}[(D^-)^3] + o(1) \quad (37)$$

as  $\theta \downarrow 0$ . Integrating eq. (37) with respect to  $\theta$  and applying Fubini's theorem gives

$$\int_0^\theta \mathbb{E}[(D^-)^3 e^{-\theta' D^-}] d\theta' = \int_0^\theta (\mathbb{E}[(D^-)^3] + o(1)) d\theta \quad (38)$$

$$\iff \mathbb{E} \left[ \int_0^\theta (D^-)^3 e^{-\theta' D^-} d\theta' \right] = \mathbb{E}[(D^-)^3] \theta + o(\theta) \quad (39)$$

$$\iff \mathbb{E}[(D^-)^2] - \mathbb{E}[(D^-)^2 e^{-\theta D^-}] = \mathbb{E}[(D^-)^3] \theta + o(\theta) \quad (40)$$

$$\iff \mathbb{E}[(D^-)^2 e^{-\theta D^-}] = \mathbb{E}[(D^-)^2] - \mathbb{E}[(D^-)^3] \theta + o(\theta). \quad (41)$$

Repeating this method yields

$$\mathbb{E}[D^- e^{-\theta D^-}] = \mu - \mathbb{E}[(D^-)^2] \theta + \frac{1}{2} \mathbb{E}[(D^-)^3] \theta^2 + o(\theta^2), \quad (42)$$

$$\text{and} \quad \mathbb{E}[e^{-\theta D^-}] = 1 - \mu\theta + \frac{1}{2} \mathbb{E}[(D^-)^2] \theta^2 - \frac{1}{6} \mathbb{E}[(D^-)^3] \theta^3 + o(\theta^3). \quad (43)$$

Similary integrating the equation

$$\mathbb{E}[(D^-)^2 D^+ \exp(-\theta D^-)] = \mathbb{E}[(D^-)^2 D^+] + o(1) \quad (44)$$

gives

$$\mathbb{E}[D^- D^+ e^{-\theta D^-}] = \mathbb{E}[D^- D^+] - \mathbb{E}[(D^-)^2 D^+] \theta + o(\theta), \quad (45)$$

$$\text{and} \quad \mathbb{E}[D^+ e^{-\theta D^-}] = \mu\theta - \mathbb{E}[D^- D^+] \theta + \frac{1}{2} \mathbb{E}[(D^-)^2 D^+] \theta^2 + o(\theta^2). \quad (46)$$

Integrating the equation

$$\mathbb{E} [D^- (D^+)^2 \exp(-\theta D^-)] = \mathbb{E} [D^- (D^+)^2] + o(1) \quad (47)$$

gives

$$\mathbb{E} [(D^+)^2 e^{-\theta D^-}] = \mathbb{E} [(D^+)^2] - \mathbb{E} [D^- (D^+)^2] \theta + o(\theta). \quad (48)$$

eq. (43) gives the expansion of the normalising constant of the measure change. Taking the logarithm on both sides of eq. (43) and expanding the right hand side gives the expansion for the cumulant generating function. Combining this with eq. (42) and eq. (46) gives the expansions for  $\mathbb{E}_\theta[D^-]$  and  $\mathbb{E}_\theta[D^+]$  respectively. Similarly eq. (41), eq. (48) and eq. (45) are used to get the expansions for  $\text{var}_\theta(D^-)$ ,  $\text{var}_\theta(D^+)$  and  $\text{cov}_\theta(D^-, D^+)$  respectively.  $\square$

### 3.2 Local limit theorems

Next we recall a local limit theorem for triangular arrays on lattices. For this section it is convenient to view all the variables as living in the same probability space rather than applying a measure change.

#### Lemma 2

Writing  $\tilde{\sigma}^2 = \text{var}(D^- - D^+)$ ,

$$\mathbb{P}_n \left( \Delta_{n-m} = \sum_{i=1}^m (k_i^+ - k_i^-) \right) \sim \mathbb{P}(\Delta_n = 0) \sim \frac{1}{\sqrt{2\pi\tilde{\sigma}^2 n}} \quad (49)$$

as  $n \rightarrow \infty$ .

When expanding the measure change, instead of expanding in terms of  $\Xi_{n-m}^-$  it is convenient to expand in terms of  $\Omega_n^-$  which is almost  $\mathbb{P}_n$ -centered. The following lemma provides probabilistic bounds on  $\Omega_n^-$ .

#### Lemma 3

Define

$$\Omega_n^- := \Xi_{n-m}^- - \mu n + \nu_- m. \quad (50)$$

Then

$$\lim_{n \rightarrow \infty} \mathbb{P}_n \left( |\Omega_n^-| \leq n^{\frac{1}{2} + \epsilon} \mid \Delta_{n-m} = \sum_{i=1}^m (k_i^+ - k_i^-) \right) = 1. \quad (51)$$

### 3.3 Combining the parts

*Proof.* Firstly

$$\prod_{i=1}^m \frac{(n-i+1)\mu}{\sum_{k=i}^m k_i^- + \Xi_{n-m}^-} = \exp(X_n - Y_n) \quad (52)$$

where

$$X_n = \sum_{i=1}^m \log \left( 1 - \frac{i-1}{n} \right) \quad \text{and} \quad Y_n = \sum_{i=1}^m \log \left( \frac{\sum_{k=i}^m k_i^- + \Xi_{n-m}^-}{\mu n} \right). \quad (53)$$

Note

$$\sum_{j=i}^m k_j^- = s^-(m) - s^-(i-1) + (m-i+1)\nu_- \quad (54)$$

Thus

$$Y_n = \sum_{i=1}^m \log \left( \frac{s^-(m) - s^-(i-1) + (m-i+1)\nu_- + \Omega_n^- + \mu n - \nu_- m}{\mu n} \right) \quad (55)$$

$$= \sum_{i=1}^m \log (1 + A_n^i + B_n + C_n^i) \quad (56)$$

where

$$A_n^i = -\frac{1}{\mu} \frac{1}{n} [s^-(i-1) - s^-(m)], \quad B_n = \frac{1}{\mu} \frac{1}{n} \Omega_n^-, \quad C_n^i = -\frac{\nu_-}{\mu} \frac{1}{n} (i-1). \quad (57)$$

When expanding  $\log(1 + A_n^i + B_n + C_n^i)$ , the summation contributes order  $m = O(n^{2/3})$ . Thus we keep terms of order  $\Omega(n^{-2/3})$  in the expansion. Write

$$\mathcal{E}_n := \left\{ |\Omega_n^-| \leq n^{\frac{1}{2}+\epsilon} \right\} \quad (58)$$

On the event  $\mathcal{E}_n$ , we can check that the  $A_n, B_n, C_n^i$  and  $(C_n^i)^2$  terms are the only terms in the expansion which has order  $\Omega(n^{-2/3})$ , moreover

$$\sum_{i=1}^m C_n^i = -\frac{\nu_-}{2\mu} \frac{m^2}{n} + o(1) \quad \text{and} \quad \sum_{i=1}^m (C_n^i)^2 = \frac{\nu_-^2}{3\mu^2} \frac{m^3}{n^2} + o(1). \quad (59)$$

Therefore

$$Y_n = \sum_{i=1}^m (A_n^i + B_n + C_n^i - \frac{1}{2}(C_n^i)^2) + o(1) \quad (60)$$

$$= -\frac{1}{\mu} \frac{1}{n} \sum_{i=0}^m (s^-(i) - s^-(m)) + \frac{1}{\mu} \frac{m}{n} \Omega_n^- - \frac{\nu_-}{2\mu} \frac{m^2}{n} - \frac{\nu_-^2}{6\mu^2} \frac{m^3}{n^2} + o(1). \quad (61)$$

where we use that  $\sum_{i=1}^m (s^-(i-1) - s^-(m)) = \sum_{i=0}^m (s^-(i) - s^-(m))$ .

Similarly we can expand  $X_n$  as

$$X_n = -\frac{1}{2} \frac{m}{n} - \frac{1}{3} \frac{m^3}{n^2} + o(1). \quad (62)$$

Thus

$$\prod_{i=1}^m \frac{(n-i+1)\mu}{\sum_{k=i}^m k_i^- + \Xi_{n-m}^-} \geq \exp \left( \frac{1}{\mu} \frac{1}{n} \sum_{i=1}^m (s^-(i) - s^-(m)) - \frac{1}{\mu} \frac{m}{n} \Omega_n^- + \frac{\nu_- - \mu}{2\mu} \frac{m^2}{n} + \frac{\nu_-^2 - \mu^2}{6\mu^2} \frac{m^3}{n^2} \right) \mathbb{1}_{\mathcal{E}_n} \quad (63)$$

In addition measure change can be expanded as

$$\frac{d\mathbb{P}_n}{d\mathbb{P}} = \exp \left( -\frac{1}{\mu} \frac{m}{n} \Omega_n^- + \frac{\nu_- - \mu}{2\mu} \frac{m^2}{n} + \frac{\nu_-^2 - \mu^2}{6\mu^2} \frac{m^3}{n^2} + \frac{\sigma_-^2}{6\mu^2} \frac{m^3}{n^2} + o(1) \right). \quad (64)$$

Hence

$$\phi_m^n(\mathbf{k}_1, \dots, \mathbf{k}_m) \quad (65)$$

$$= \frac{1}{\mathbb{P}(\Delta_n = 0)} \mathbb{E} \left[ \prod_{i=1}^m \frac{(n-i+1)\mu}{\sum_{k=i}^m k_i^- + \Xi_{n-m}^-} \mathbb{1}_{A_n} \right] \quad (66)$$

$$\geq \frac{1}{\mathbb{P}(\Delta_n = 0)} \mathbb{E}_n \left[ \exp \left( \frac{1}{\mu n} \sum_{i=1}^m (s^-(i) - s^-(m)) - \frac{\sigma_-^2}{6\mu^2} \frac{m^3}{n^2} + o(1) \right) \mathbb{1}_{\mathcal{E}_n \cap A_n} \right] \quad (67)$$

$$\geq \exp \left( \frac{1}{\mu n} \sum_{i=1}^m (s^-(i) - s^-(m)) - \frac{\sigma_-^2}{6\mu^2} \frac{m^3}{n^2} \right) (1 + o(1)) \frac{\mathbb{P}_n(\mathcal{E} \cap A_n)}{\mathbb{P}(\Delta_n = 0)}. \quad (68)$$

Finally

$$\frac{\mathbb{P}_n(\mathcal{E} \cap A_n)}{\mathbb{P}(\Delta_n = 0)} = \mathbb{P}_n(\mathcal{E} \mid A_n) \frac{\mathbb{P}_n(A_n)}{\mathbb{P}(\Delta_n = 0)} \rightarrow 1 \quad (69)$$

as  $n \rightarrow \infty$  by INSERT REFERENCE and INSERT REFERENCE which gives the desired final result.  $\square$
